ABSTRACT
CROSS-SECTIONAL ANALYSIS OF TELOMERE LENGTH IN PEOPLE 33-38 YEARS OF AGE: EFFECTS OF DIETARY SUPPLEMENTATION

Telomere length has been associated with aging, age-related diseases, adverse conditions, and mortality. Moreover, studies in humans suggest a causal role of short telomeres or accelerated telomere shortening in disease and mortality risk. A previous cross-sectional study has shown that supplement usage significantly improved various health parameters and nutritional status. The objective of the current cross-sectional study was to explore the effect of dietary supplementation on telomere length.

The normal range of telomere lengths was determined from saliva samples in a population of healthy, non-smoking subjects aged 33-38 from the San Francisco Bay Area (control group; n=324; 147 males and 177 females) who took no more than 3 supplements daily. The telomere lengths of heavy supplement users (supplement group; n=21; 25 males and 9 females), the majority of whom took more than 12 supplements at least 4 days per week, were compared to the age-matched control group.

Telomere length was measured by quantitative PCR to determine the telomere-to-single copy gene (T/S) ratio. Change in T/S ratio over time was fitted to a linear regression. Blood biomarkers were also assessed.

Overall, women had longer telomeres than men in the control group, but this trend was reversed in the supplement group. T/S ratio of the supplement group was 12.2% greater than that of the control group (p<0.0001). Supplementation resulted in a greater telomere length in men vs. women (p<0.005). By linear regression, the rate of change in T/S ratio was reduced by 40% in the supplement group vs. control. Blood biomarkers in both groups were comparable and were within the normal physiological range.

The results of this cross-sectional study suggest that heavy dietary supplementation significantly attenuated telomere shortening in subjects compared to a healthy control group. Longitudinal studies are warranted to further explore the link between nutritional supplementation and healthy aging in the context of reduced rate of telomere shortening.

METHODS
Study design: cross-sectional study
Population: 1) Control group – San Francisco Bay Area healthy male and female non-smokers aged 30-80 who took no more than 3 supplements daily. 2) Supplement group – heavy supplement users aged 30-80 who took at least 5 supplements 4-6 times weekly for at least 5 years regardless of their health and/or smoking status. Participants in this group were from all regions of the country.
Recruitment: 1) Control group – recruited through agreements with local community centers and the use of social media. 2) Supplement group – recruited at the Shaklee 2012 Leadership Conference held in San Francisco.
Inclusion criteria: 1) Control group – healthy men and women aged 30-80 residing in San Francisco who were English-speaking and willing to sign the informed consent form (ICF) and keep healthy behaviors stable for one year. 2) Supplement group – men and women aged 30-80 residing in mainland USA who used at least 5 supplements 4-6 times weekly for at least 5 years and were willing to sign the ICF.
Exclusion criteria: 1) Control group – those with health conditions and taking medications that would affect telomere length, all smokers (cigarettes or recreational drugs), BMI<35, people taking more than 3 daily supplements. 2) Supplement group – no exclusion if inclusion criteria were satisfied.
Study site: sample collection and processing as well as telomere length assay and data collection were performed by Telomere Diagnostics, Menlo Park, CA.
Telomere length test: qPCR was used to measure average telomere length per genome (i.e. telomere-to-single copy gene (T/S) ratio) in saliva cellular DNA. Saliva was used because of its ease of collection and storage. Saliva samples were collected with Oragene DNA collection kit (Ont., Canada).
Statistics: Telomere length was reported as a T/S ratio (telomere signal normalized relative to a single copy gene signal). T/S ratios of the supplement group were compared to those in the age-matched control group. Student’s t-test was used for comparisons between two endpoints. For comparison of multiple endpoints, ANOVA was used. P-values less than 0.05 were considered to be statistically significant.

SUMMARY
- Demographic data showed that on average, the control group was younger than the supplement group even though the two groups were age-matched (Table 1).
- Participants in the supplement group were heavy supplement users who took more than 12 supplements at least 4 days per week for at least 10 years; much higher than the minimum requirements stipulated in the inclusion criteria.
- Supplement group had significantly higher total iron, total iron binding capacity and fasting glucose levels than those in the control group; however, these values were within normal range.
- No significant difference in blood triglyceride concentration or cholesterol ratio was observed between the control and supplement group (Table 1).
- Supplement group had significantly greater T/S ratio compared to control group (Fig. 1).
- Women had longer telomeres than men in the control group, but this trend was reversed in the supplement group (Fig. 1).
- T/S ratio of the supplement group was 11.2% greater than that of the control group (p<0.0001). Supplementation resulted in a greater treatment effect in men vs. women (p=0.0005) (Table 2).
- Linear regression indicated that the rate of change in T/S ratio was reduced by 40% in the supplement group vs control (Fig. 2).

CONCLUSIONS
- The results of this cross-sectional study suggest that dietary supplementation significantly attenuated telomere shortening.
- Longitudinal studies are warranted to further explore the link between nutritional supplementation and healthy aging in the context of reduced rate of telomere shortening.
